

Pointer Analysis

G. Ramalingam
Microsoft Research, India
&
K. V. Raghavan

Goals

- *Points-to Analysis*: Determine the set of possible values of a pointer-variable (at different points in a program)
 - what locations can a pointer point-to?
- *Alias Analysis*: Determine if two pointer-variables may point to the same location
- Compute conservative approximation
- A fundamental analysis, required by most other static analyses

A Constant Propagation Example

```
x = 3;  
y = 4;  
z = x + 5;
```

- x is always 3 here
- can replace x by 3
- and replace $x+5$ by 8
- and so on

A Constant Propagation Example With Pointers

```
x = 3;  
  
*p = 4;  
  
z = x + 5;
```

- Is *x* always 3 here?

A Constant Propagation Example With Pointers

```
p = &y;  
x = 3;  
*p = 4;  
z = (x) + 5;
```

x is always

```
if (?)  
  p = &x;  
else  
  p = &y;  
x = 3;
```

pointers affect
most program analyses

```
p = &x;  
x = 3;  
*p = 4;  
z = (x) + 5;
```

always 4

x may be 3 or 4
(i.e., x is unknown in our lattice)

A Constant Propagation Example With Pointers

```
p = &y;  
x = 3;  
*p = 4;  
z = x + 5;
```

p always
points-to *y*

```
if (?)  
  p = &x;  
else  
  p = &y;  
x = 3;  
*p = 4;  
z = x + 5;
```

p may point-to *x* or *y*

```
p = &x;  
x = 3;  
*p = 4;  
z = x + 5;
```

p always
points-to *x*

Points-to Analysis

- Determine the set of targets a pointer variable could point-to (at different points in the program)
 - “ p points-to x ”
 - “ p stores the value $\&x$ ”
 - “ $*p$ denotes the location x ”
 - targets could be variables or locations in the heap (dynamic memory allocation)
 - $p = \&x;$
 - $p = \text{new Foo}();$ or $p = \text{malloc} (...);$

Algorithm A (may points-to analysis) A Simple Example

```
p = &x;  
q = &y;  
if (?) {  
    q = p;  
}  
x = &a;  
y = &b;  
z = *q;
```

Algorithm A (may points-to analysis)

A Simple Example

```
x = &a;  
y = &b;  
if (?) {  
  p = &x;  
} else {  
  p = &y;  
}
```

```
*x = &c;  
*p = &c;
```

How should we handle this statement? (Try it!)

Weak update

Strong update

x: a	y: b	p: {x,y}	a: null
x: a	y: b	p: {x,y}	a: c
x: {a,c}	y: {b,c}	p: {x,y}	a: c

Questions

- When is it **correct** to use a strong update? A weak update?
- Is this points-to analysis **precise**?
- We must **formally** define what we want to compute before we can answer many such questions

Points-To Analysis: An Informal Definition

- Let u denote a program-point
- Define $IdealMayPT(u)$ to be
 $\{ (p,x) \mid p \text{ points-to } x \text{ in some state at } u \text{ in some run} \}$
- Algorithm should compute a set $MayPT(u)$ that over-approximates above set

Static Program Analysis

- A static program analysis computes **approximate information** about the **runtime behavior** of a given **program**
 1. The **set of valid programs** is defined by the **programming language syntax**
 2. The **runtime behavior** of a given program is defined by the **programming language semantics**
 3. The **analysis problem** defines **what information** is desired
 4. The **analysis algorithm** determines what **approximation** to make

Programming Language: Syntax

- A program consists of
 - a set of variables Var
 - a directed graph $(V, E, entry)$ with a distinguished entry vertex, with every edge labelled by a primitive statement
- A primitive statement is of the form

- $x = null$
- $x = y$
- $x = *y$
- $x = \&y;$
- $*x = y$
- $skip$

Omitted (for now)

- Dynamic memory allocation
- Pointer arithmetic
- Structures and fields
- Procedures

(where x and y are variables in Var)

Example Program

```
x = &a;  
y = &b;  
if (?) {  
    p = &x;  
} else {  
    p = &y;  
}
```

```
*x = &c;  
*p = &c;
```

Vars = {x,y,p,a,b,c}

Programming Language: Operational Semantics

- Operational semantics == an interpreter (defined mathematically)
- State
 - $\text{DataState} ::= \text{Var} \rightarrow (\text{Var} \cup \{\text{null}\})$
 - $\text{PC} ::= V$ (the vertex set of the CFG)
 - $\text{ProgramState} ::= \text{PC} \times \text{DataState}$
- Initial-state:
 - $(\text{entry}, \lambda x. \text{null})$

Example States

Vars = {x,y,p,a,b,c}

Initial data-state

$x: N, y: N, p: N, a: N, b: N, c: N$

Initial program-state

$\langle 1, x: N, y: N, p: N, a: N, b: N, c: N \rangle$

Next program-state

$\langle 2, x: a, y: N, p: N, a: N, b: N, c: N \rangle$

Programming Language: Operational Semantics

- Meaning of primitive statements
 - $CS[stmt] : DataState \rightarrow 2^{DataState}$

- $CS[x = null] s = \{s[x \rightarrow null]\}$

- $CS[x = \&y] s = \{s[x \rightarrow y]\}$

- $CS[x = y] s = \{s[x \rightarrow s(y)]\}$

- $CS[x = *y] s = \dots$

...

- $CS[*x = y] s = \dots$

...

= ...

Programming Language: Operational Semantics

- Meaning of primitive statements

– $CS[stmt] : DataState \rightarrow 2^{DataState}$

- $CS[x = null] s = \{s[x \rightarrow null]\}$
- $CS[x = \&y] s = \{s[x \rightarrow y]\}$
- $CS[x = y] s = \{s[x \rightarrow s(y)]\}$
- $CS[x = *y] s = \{s[x \rightarrow s(s(y))]\}$,
if $s(y)$ is not null
= $\{\}$, otherwise
- $CS[*x = y] s = \dots$
...
...

Programming Language: Operational Semantics

- Meaning of primitive statements
 - $CS[stmt] : DataState \rightarrow 2^{DataState}$

- $CS[x = null] s = \{s[x \rightarrow null]\}$
- $CS[x = \&y] s = \{s[x \rightarrow y]\}$
- $CS[x = y] s = \{s[x \rightarrow s(y)]\}$
- $CS[x = *y] s = \{s[x \rightarrow s(s(y))]\}$,
if $s(y)$ is not null
= $\{\}$, otherwise
- $CS[*x = y] s = \{s[s(x) \rightarrow s(y)]\}$,
if $s(x)$ is not null
= $\{\}$, otherwise

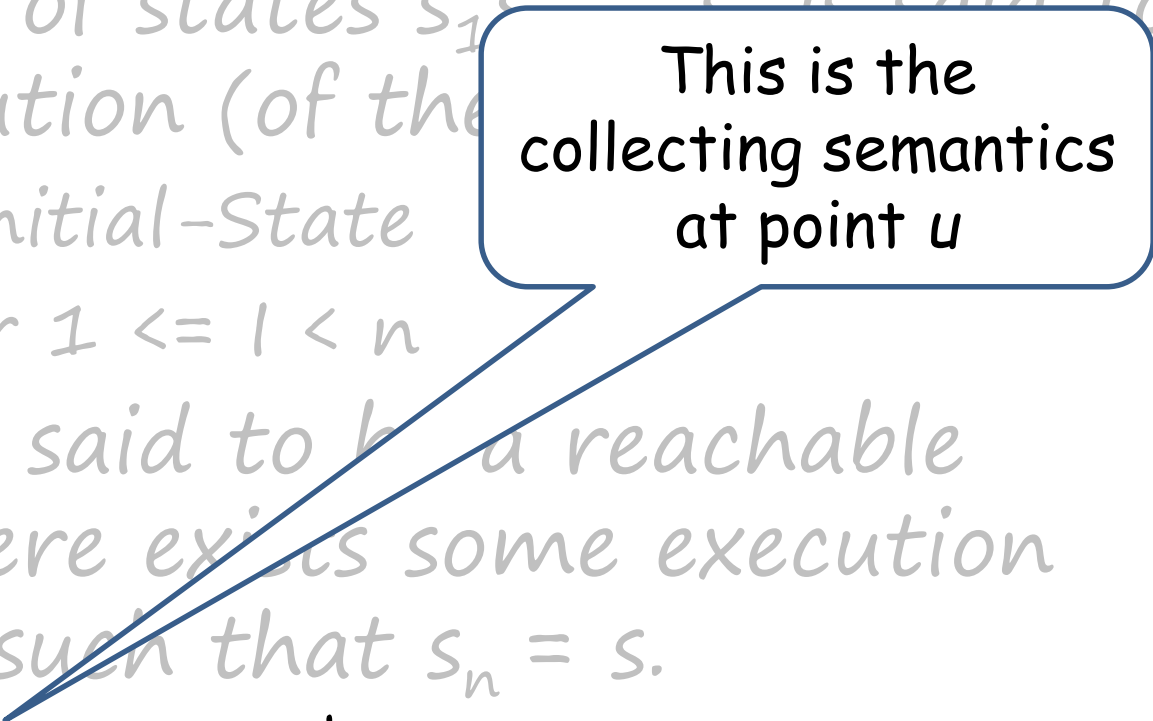

Programming Language: Operational Semantics

- Meaning of program
 - a transition relation \rightarrow on program-states
 - $\rightarrow \subseteq \text{ProgramState} \times \text{ProgramState}$
 - $\text{state}_1 \rightarrow \text{state}_2$ means that the execution of some edge in the program can transform state_1 into state_2
- Defining \rightarrow
 - $(u, s) \rightarrow (v, s')$ iff the program contains a control-flow edge $u \rightarrow v$ labelled with a statement stmt such that s' in $CS[\text{stmt}]s$

Programming Language: Operational Semantics

- A sequence of states $s_1 s_2 \dots s_n$ is said to be an **execution** (of the program) iff
 - s_1 is the Initial-State
 - $s_i \rightarrow s_{i+1}$ for $1 \leq i < n$
- A state s is said to be a **reachable state** iff there exists some execution $s_1 s_2 \dots s_n$ is such that $s_n = s$.
- Define **RS**(u) = { s | (u, s) is reachable }

Programming Language: Operational Semantics

- A sequence of states $s_1 s_2 \dots s_n$ is said to be an execution (of the program) if:
 - s_1 is the Initial-State
 - $s_i \rightarrow s_{i+1}$ for $1 \leq i < n$
 - A state s is said to be a reachable state iff there exists some execution $s_1 s_2 \dots s_n$ such that $s_n = s$.
 - Define $RS(u) = \{ s \mid (u, s) \text{ is reachable} \}$
- 
- This is the collecting semantics at point u

Ideal Points-To Analysis: Formal Definition

- Let u denote a vertex in the CFG
- Define $\text{IdealMayPT}(u)$ to be
 $\bigcup p. \{ x \mid \text{exists } s \text{ in } RS(u). s(p) == x \}$

May-Point-To Analysis: Problem statement

Compute $\text{MayPT}: V \rightarrow 2^{\text{Var}'}$ such
that for every vertex u
 $\text{MayPT}(u) \supseteq \text{IdealMayPT}(u)$
(where $\text{Var}' = \text{Var} \cup \{\text{null}\}$)

May-Point-To Algorithms

Compute MayPT: $V \rightarrow 2^{\text{Vars}}$ such
that
 $\text{MayPT}(u) \supseteq \text{IdealMayPT}(u)$

- An algorithm is said to be **correct** if the solution MayPT it computes satisfies
 $\forall u \in V. \text{MayPT}(u) \supseteq \text{IdealMayPT}(u)$
- An algorithm is said to be **precise** if the solution MayPT it computes satisfies
 $\forall u \in V. \text{MayPT}(u) = \text{IdealMayPT}(u)$
- An algorithm that computes a solution MayPT1 is said to be **more precise** than one that computes a solution MayPT2 if
 $\forall u \in V. \text{MayPT1}(u) \subseteq \text{MayPT2}(u)$

Algorithm A: A Formal Definition The “Data Flow Analysis” Recipe

- Define semi-lattice of abstract-values
 - $\text{AbsDataState} ::=$
 $(\text{Var} \rightarrow (2^{\text{Var}} - \{\})) \cup \{\text{bot}\}$
 - $f_1 \cup f_2 = \lambda x. (f_1(x) \cup f_2(x))$
- Define initial abstract-value
 - $\text{InitialAbsState} = \lambda x. \{\text{null}\}$
- Define transformers for primitive statements
 - $\text{AS}[\text{stmt}] : \text{AbsDataState} \rightarrow \text{AbsDataState}$

Algorithm A: A Formal Definition

The “Data Flow Analysis” Recipe

- Apply Kildall’s algorithm, using `AbsDataState` lattice, and AS transfer functions.

Algorithm A: The Transformers

- Abstract transformers for primitive statements
 - $AS[stmt] : AbsDataState \rightarrow AbsDataState$
- $AS[x = y] s = s[x \rightarrow s(y)]$
- $AS[x = null] s = s[x \rightarrow \{null\}]$
- $AS[x = \&y] s = s[x \rightarrow \{y\}]$
- $AS[x = *y] s = s[x \rightarrow s^*(s(y) - \{null\})],$
if $s(y)$ is not $= \{null\}$
 $= bot$, otherwise

where $s^*(\{v_1, \dots, v_n\}) = s(v_1) \cup \dots \cup s(v_n),$

Algorithm A

• $AS[*x = y] s =$

$\left\{ \begin{array}{ll} \text{bot} & \text{if } s(x) = \{\text{null}\} \\ s[z \rightarrow s(y)] & \text{if } s(x) - \{\text{null}\} = \{z\} \\ \\ s[z_1 \rightarrow s(z_1) \cup s(y)] & \text{if } s(x) - \{\text{null}\} = \{z_1, \dots, z_k\} \\ [z_2 \rightarrow s(z_2) \cup s(y)] & \text{(where } k > 1) \\ \dots & \\ [z_k \rightarrow s(z_k) \cup s(y)] & \end{array} \right.$

• After fix-point solution is obtained, $AbsDataState(u)$ is emitted as $MayPT(u)$, for each program point u

An alternative algorithm: must points-to analysis

- *AbsDataState* is modified, as follows:
 - Each var is mapped to $\{\}$ or to a singleton set
 - join is point-wise intersection
- Let $\text{MustPT}(u)$ be fix-point at u
- Guarantee: $\Upsilon(\text{MustPT}(u)) \supseteq \text{MayPT}(u) \supseteq \text{IdealMayPT}(u)$

where $\Upsilon(S) = S$,
if S is a singleton set
 $= \text{Var}'$, if $S = \{\}$

Must points-to analysis algorithm

- AS transfer functions same as in Algorithm A for $x = y$, $x = \text{null}$, and $x = \&y$
- $AS[x = *y] s$
 - = bot, if $s(y) = \{\text{null}\}$
 - = $s[x \rightarrow \{\}]$, if $s(y) = \{\}$
 - = $s[x \rightarrow s(z)]$, if $s(y) = \{z\}$

Must points-to analysis algorithm

- $AS[*x = y] s = bot,$
 - if $s(x) = \{null\}$
 - $= s[z \rightarrow s(y)]$
 - if $s(x) = \{z\}$
 - $= \setminus v. \{\},$
 - otherwise

This analysis is less precise than the may-points-to analysis (Algorithm A), but is more efficient
