SPARK

Prasad M Deshpande

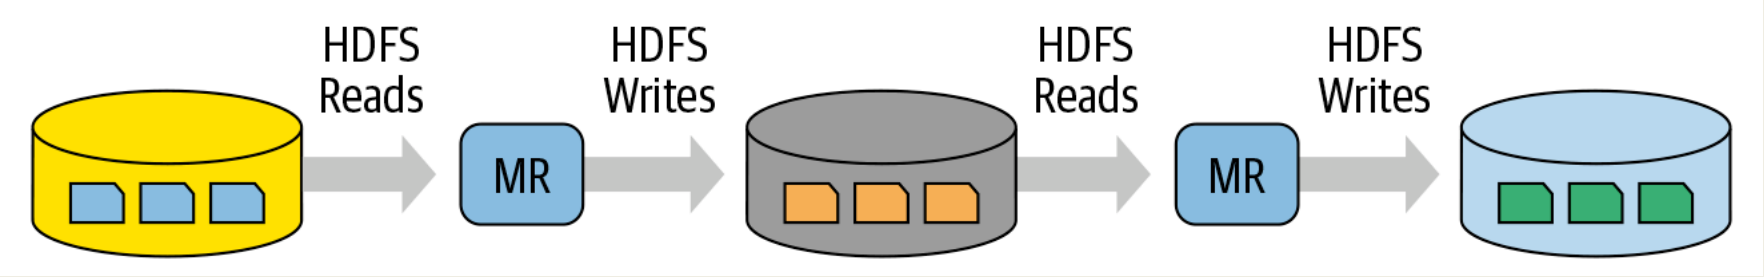
Revisiting the word count problem

Find the top 10 most frequently used words across a set of documents

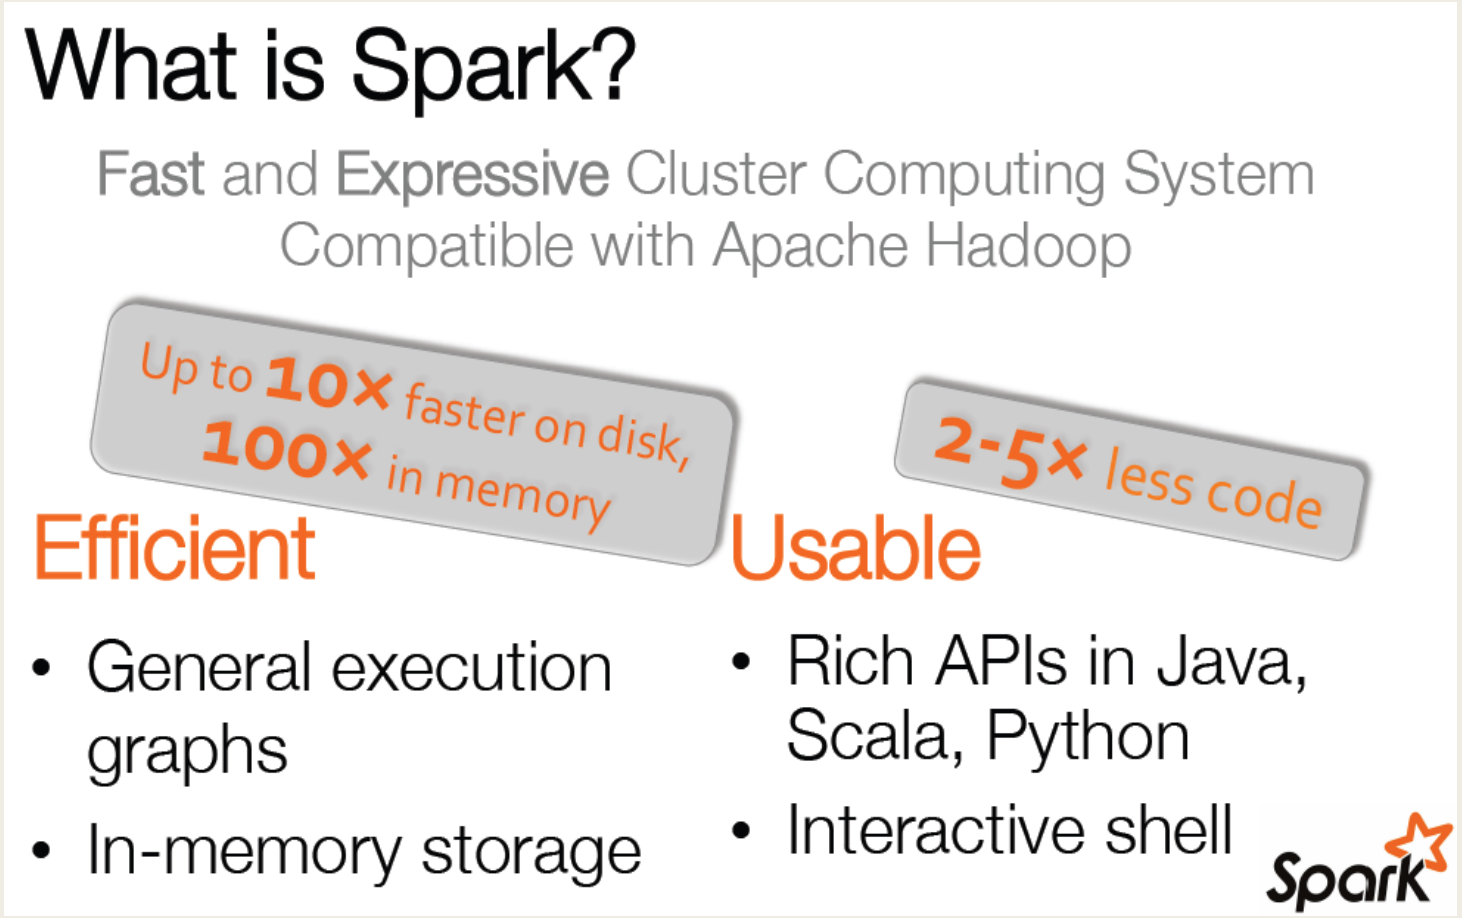
- Find the occurrence count for each word
- Find the top 10 words based on these counts

MR limitations

- Verbose API
- Low level abstraction – led to many layers built on top
  - *Hive, Impala for SQL*
  - *Storm for streaming*
  - *Giraph for graph data*
  - *Mahout for linear algebra, ML*
- Efficiency



Spark – a unified engine



From McDonough Spark tutorial from Spark Summit 2013

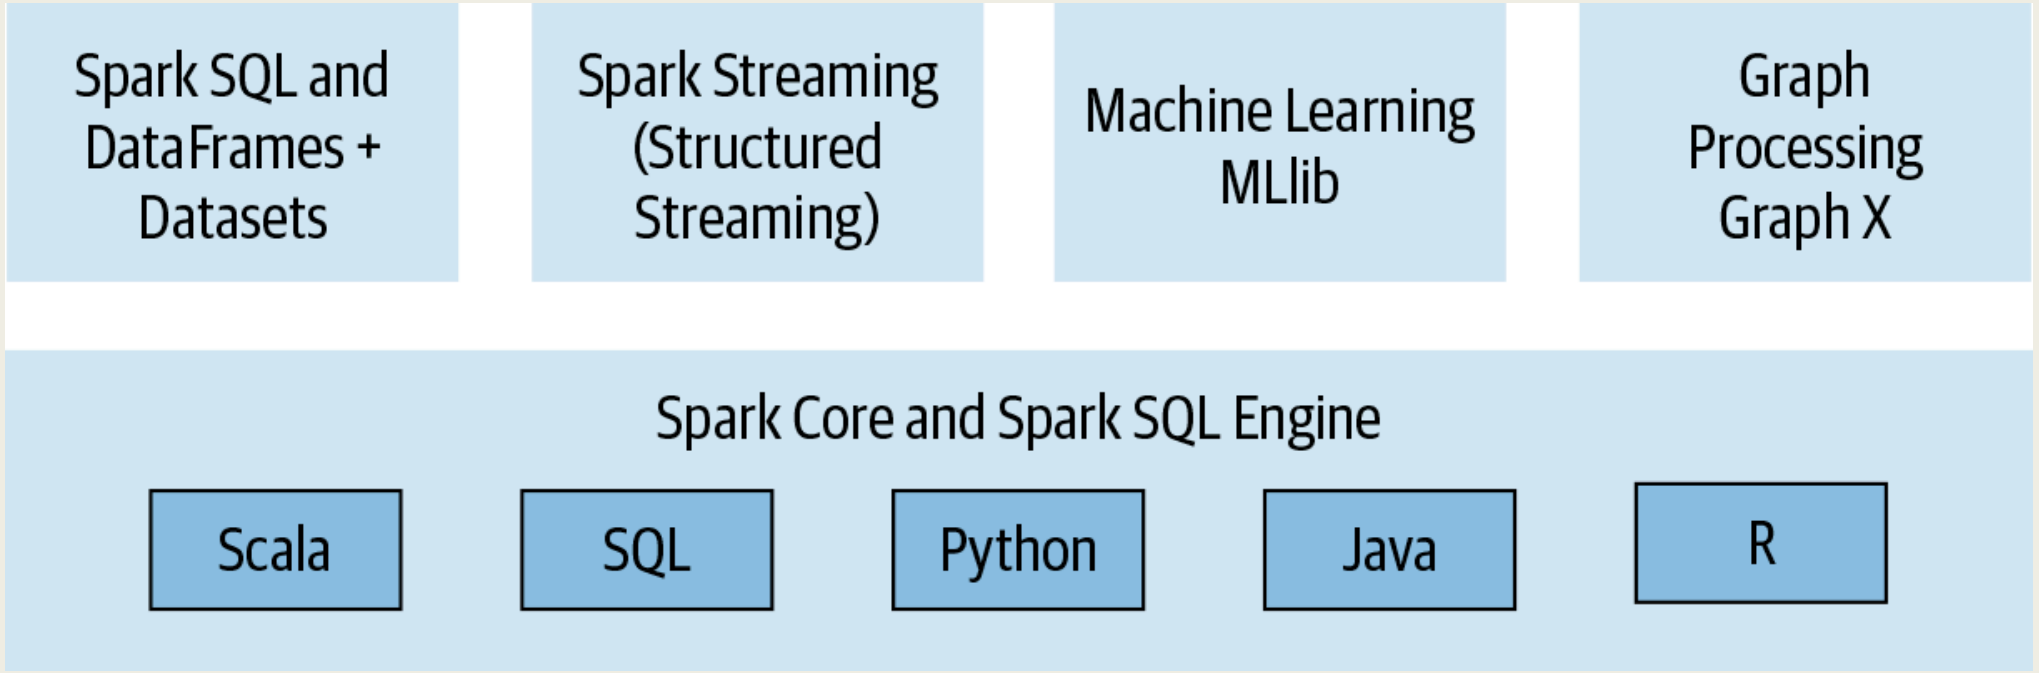
Design goals

- Speed
  - *Hold intermediate data in memory*
  - *DAG scheduler executes task in parallel*
  - *Code generation*
- Ease of use
  - *Simple abstractions RDD, DataFrame, DataSet*
  - *Operations*
- Modularity
  - *Components for various functionalities*
  - *Libraries in different languages*
- Extensibility
  - *Decouples storage and compute*
  - *Can read data from many sources – Hadoop, Cassandra, HBase, etc*

Quick comparison

Feature	MapReduce	Spark
Data Processing Location	Primarily on disk	Primarily in-memory
Processing Paradigm	Two-stage (Map & Reduce)	DAG (Directed Acyclic Graph)
Ease of Use	More complex, requires writing Java code	More user friendly. Supports multiple languages (Java, Scala, Python, R)

Unified stack



Spark Core

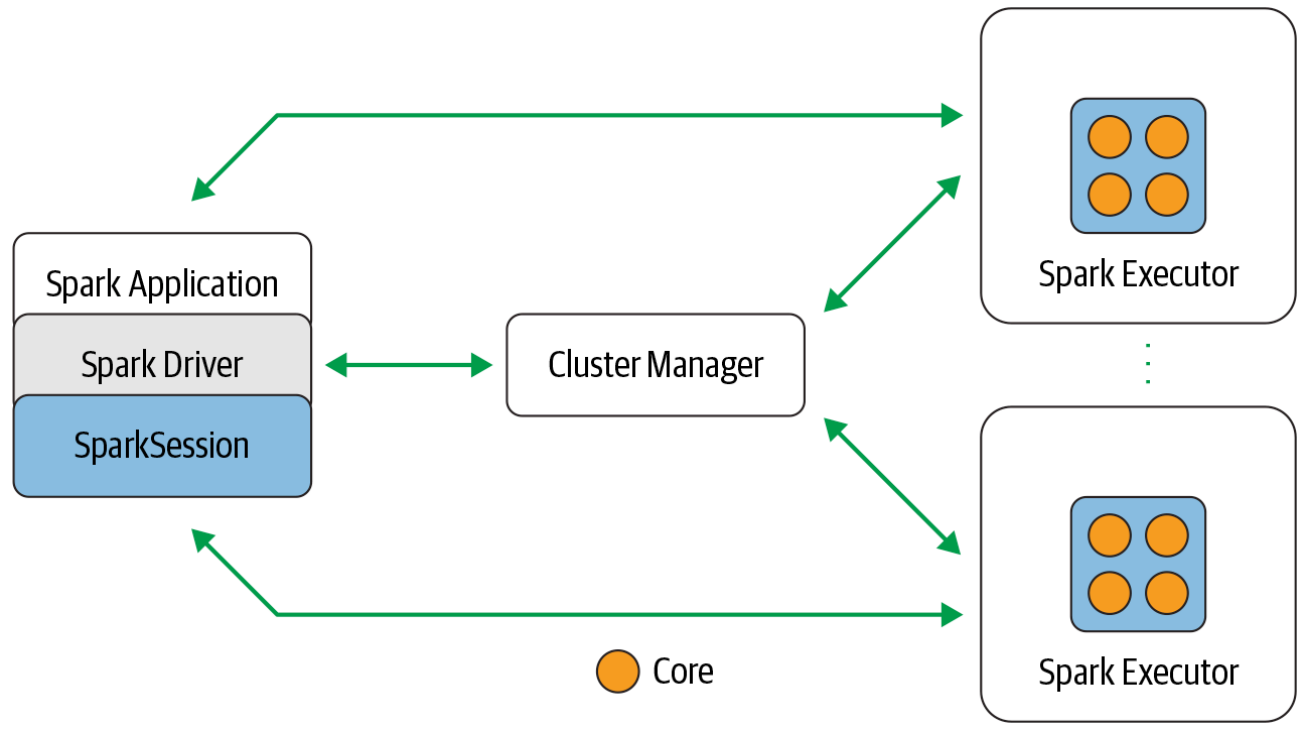
Responsible for:

✓ Memory Management and fault recovery

✓ Supports/implements key concepts of RDDs and Actions

✓ Scheduling, Monitoring, Distributing jobs on cluster [via YARN]

Architecture



Driver program

- The process running the main() function of the application and creating the SparkContext

Executor

- A process launched for an application on a worker node, that runs tasks and keeps data in memory or disk storage across them.

Spark session

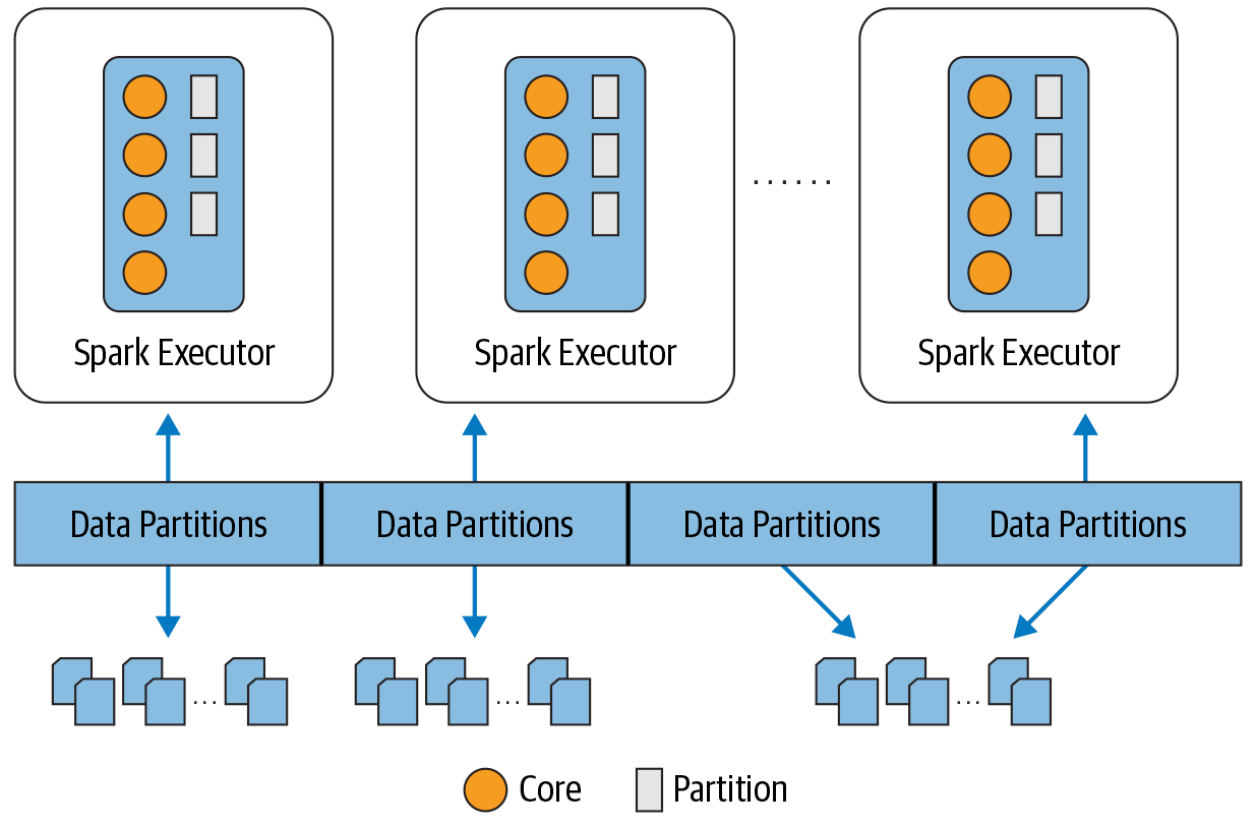
```scala
// In Scala
import org.apache.spark.sql.SparkSession

// Build SparkSession
val spark = SparkSession
  .builder
  .appName("LearnSpark")
  .config("spark.sql.shuffle.partitions", 6)
  .getOrCreate()
...
// Use the session to read JSON
val people = spark.read.json("...")
...
// Use the session to issue a SQL query
val resultsDF = spark.sql("SELECT city, pop, state, zip FROM table_name")
```

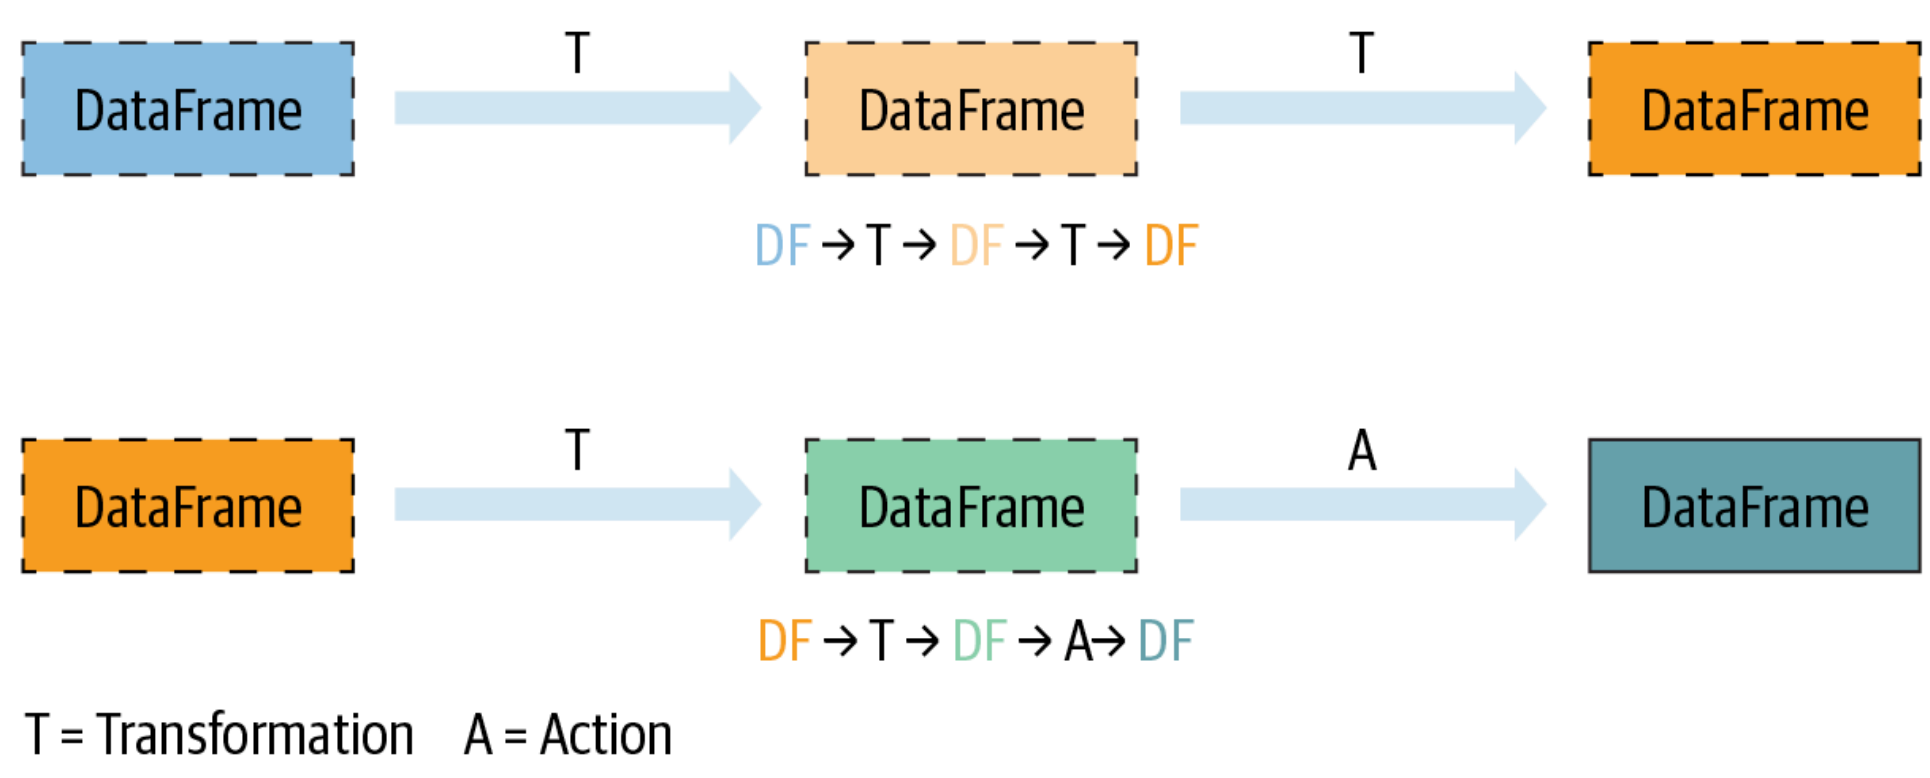
Resilient Distributed Data

- Write programs in terms of transformations on distributed datasets
- RDD – collection of objects spread across the cluster, stored in disk or memory
- Built through parallel transformations
- Automatically rebuilt on failure

Logical in memory vs Physical distribution



Lazy Transformations, Eager Actions



- Populating of blocks into memory deferred until action is invoked
- Action triggers actual evaluation of the RDD

Transformations vs Actions

Feature	Transformations	Actions
Purpose	Define data operations	Trigger computation
Output	New Spark data structure	Value or side effect
Execution	Lazy (build DAG)	Eager (execute DAG)
Example	filter, map, join	count, collect, save

Example

Transformations	Actions
orderBy()	show()
groupBy()	take()
filter()	count()
select()	collect()
join()	save()
map()	
flatmap()	

```
// In Scala
scala> import
org.apache.spark.sql.functions._
scala> val strings = spark.read.text("../
README.md")
scala> val filtered =
strings.filter(col("value").contains("Spark"
))
scala> filtered.count()
res5: Long = 20
```

Parallelizing Data

- How many partitions my RDD is split into?

```
# In Python
print(log_df.rdd.getNumPartitions())
```

- How to enforce “degree of parallelism”?

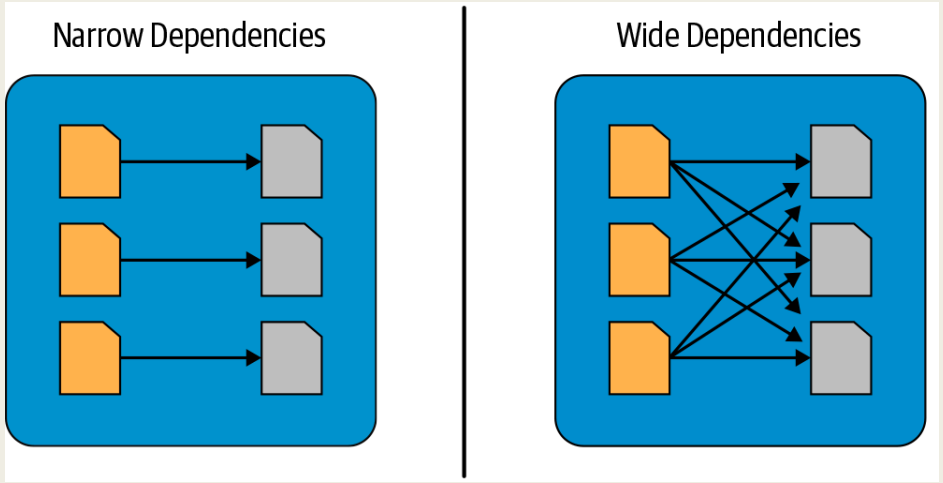
```
# In Python
log_df = spark.read.text("path_to_large_text_file").repartition(8)
print(log_df.rdd.getNumPartitions())
```

repartition vs coalesce

- `repartition` : will shuffle the original partitions and repartition them
- `coalesce` : will just combine original partitions to the new number of partitions.

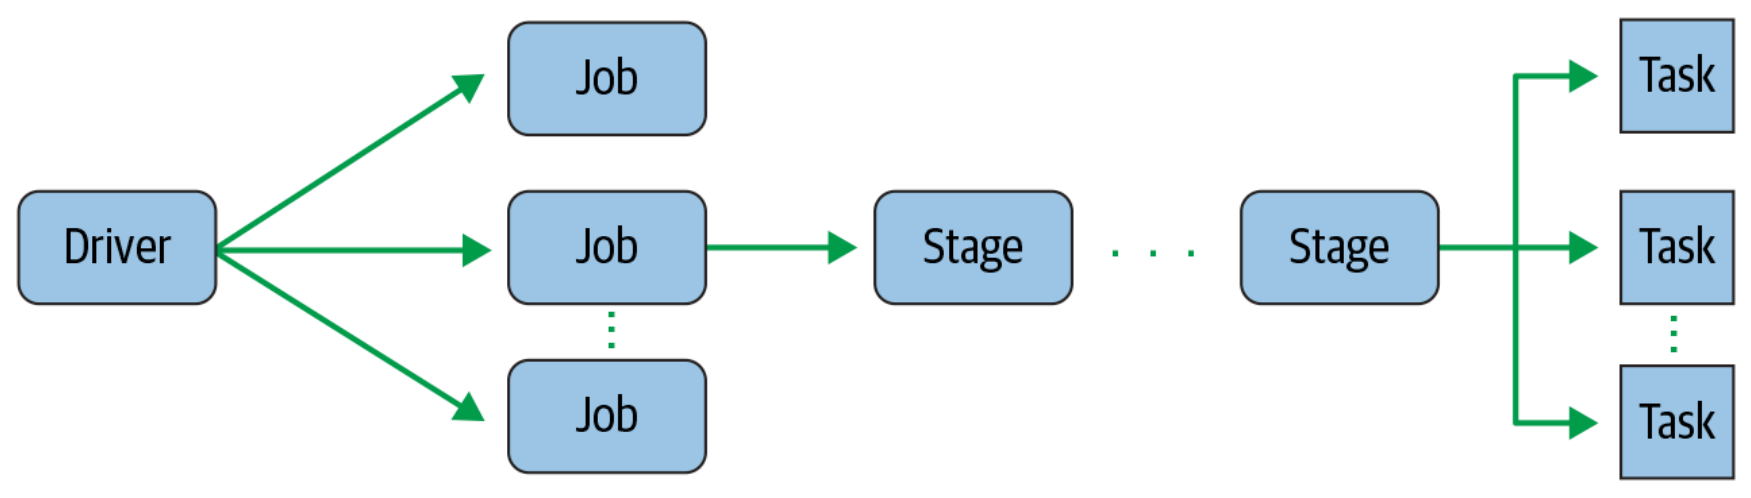
shuffling could be very costly, but can be used to both increase and decrease number of partitions
coalesce can be used to only to reduce the number of partitions

Narrow vs wide transformations



- Narrow – single output partition can be computed from a single input partition is a narrow transformation
  - *E.g. Filter*
- Wide – data from other partitions is read in, combined, and written to disk
  - *E.g. group-by*
  - *Similar to reduce of MR*

Job, Stage, Task



- Job - A logical sequence of operations on a RDD
- Stage - A sequence of operations that can be performed together without the need for shuffling
- Task - Work unit to be done on a partition

Fault tolerance

- DataFrames are immutable
- Lineage is maintained
- On failure, entire flow is run again

RDD → DataFrames→ DataSets

RDD

- characteristics
  - *Dependencies*
  - *Partitions (with some locality information)*
  - *Compute function: Partition => Iterator[T]*
- Limitations
  - *Data type is opaque to spark*
  - *Compute function is also opaque*

Dataframe

- Introduced in spark 1.3 release
- Data organized into named columns (tabular format)
- Computations expressed as high-level operations
  - *such as filtering, selecting, counting, aggregating, averaging, and grouping.*
- Spark can optimize the query plan

Example RDD and DF

```
# In Python

# Create an RDD of tuples (name, age)

dataRDD = sc.parallelize([("Brooke",
20), ("Denny", 31), ("Jules", 30),
("TD", 35), ("Brooke", 25)])

# Use map and reduceByKey
transformations with their lambda

# expressions to aggregate and then
compute average

agesRDD = (dataRDD

.map(lambda x: (x[0], (x[1], 1)))

.reduceByKey(lambda x, y: (x[0] + y[0],
x[1] + y[1]))

.map(lambda x: (x[0], x[1][0]/x[1][1])))
```

```
# Create a DataFrame

data_df =
spark.createDataFrame([("Brooke", 20),
("Denny", 31), ("Jules", 30),("TD",
35), ("Brooke", 25)], ["name", "age"])

# Group the same names together,
aggregate their ages, and compute an
average

avg_df =
data_df.groupBy("name").agg(avg("age"))

# Show the results of the final
execution

avg_df.show()
```

Dataset

- Extension of DataFrame API which provides type-safe [compile time], object-oriented programming interface
- Maps the rows in DF into user defined class
- One can seamlessly move between DataFrame or Dataset and RDDs by simple API method calls like .rdd or .toDF or .as[T]

```
case class DeviceIoTData
(battery_level: Long, c02_level:
Long,cca2: String, cca3: String, cn:
String, device_id: Long, device_name:
String, humidity: Long, ip: String,
latitude: Double, lcd: String,
longitude: Double, scale:String,
temp: Long, timestamp: Long)

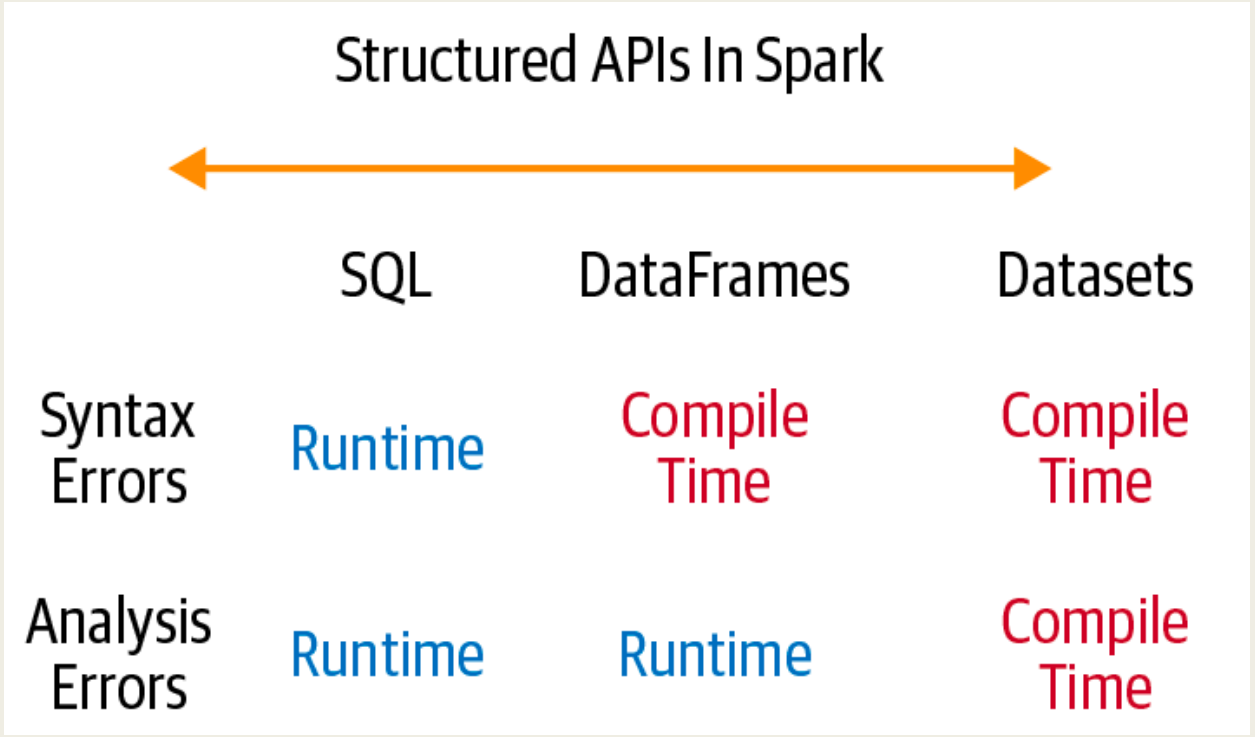
val ds = spark.read.json("/
databricks-datasets/learning-spark-
v2/iot-devices/
iot_devices.json").as[DeviceIoTData]

val filterTempDS = ds.filter({d =>
{d.temp > 30 && d.humidity > 70})
```

Dataframe vs dataset

- If you want strict compile-time type safety and don’t mind creating multiple case classes for a specific Dataset[T], use Datasets.
- If your processing dictates relational transformations similar to SQL-like queries, use DataFrames.
- If you want to take advantage of and benefit from Tungsten’s efficient serialization with Encoders, use Datasets.
- If you want unification, code optimization, and simplification of APIs across Spark components, use DataFrames.

When are errors caught?



Glimpse into Spark ML

```
val lr = new LogisticRegression().setMaxIter(10).setRegParam(0.001)

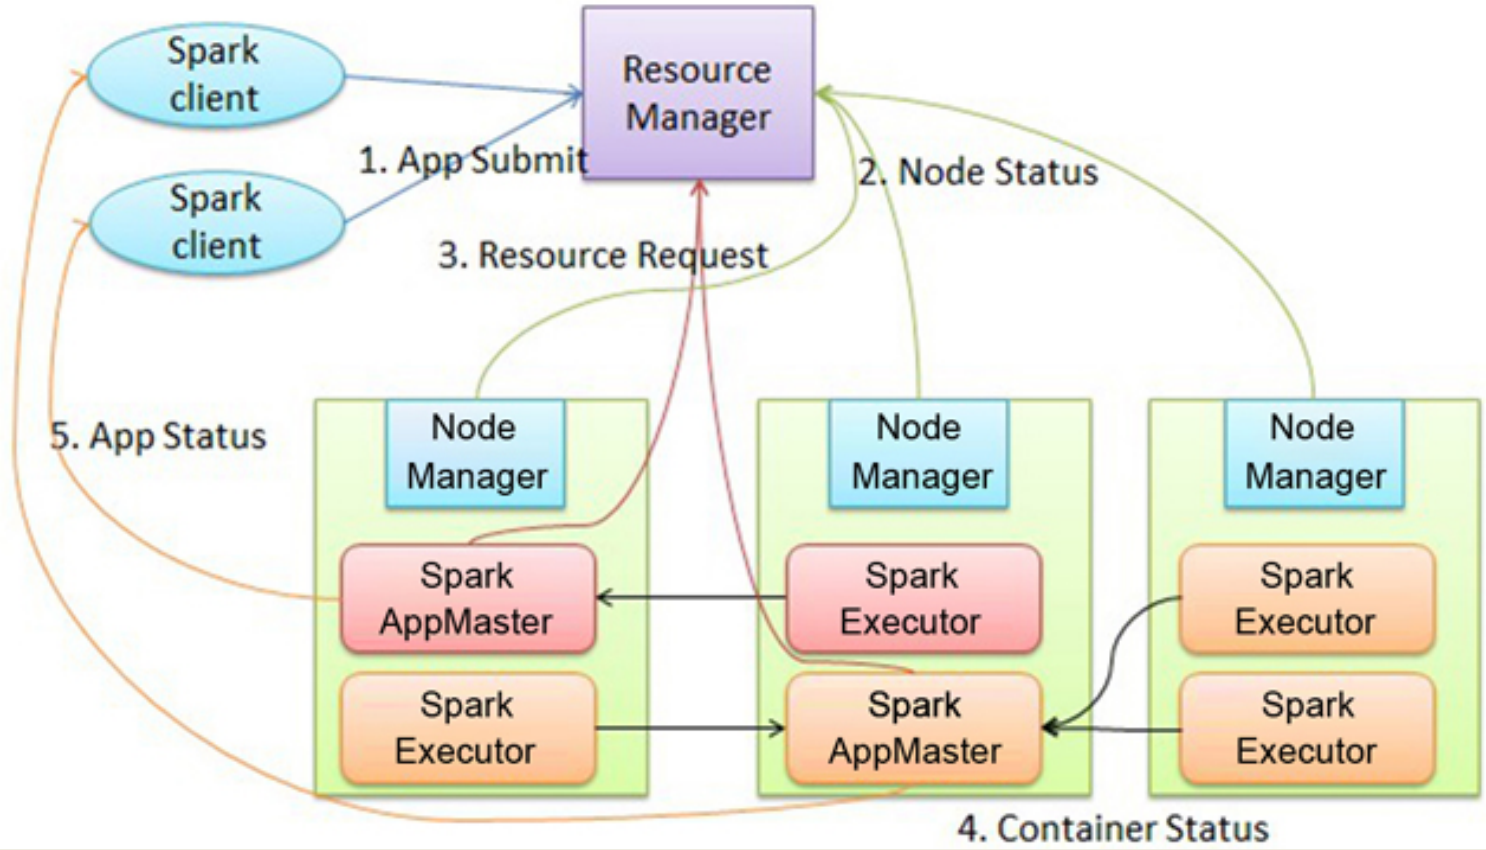
val pipeline = new Pipeline().setStages(Array(tokenizer, hashingTF, lr))

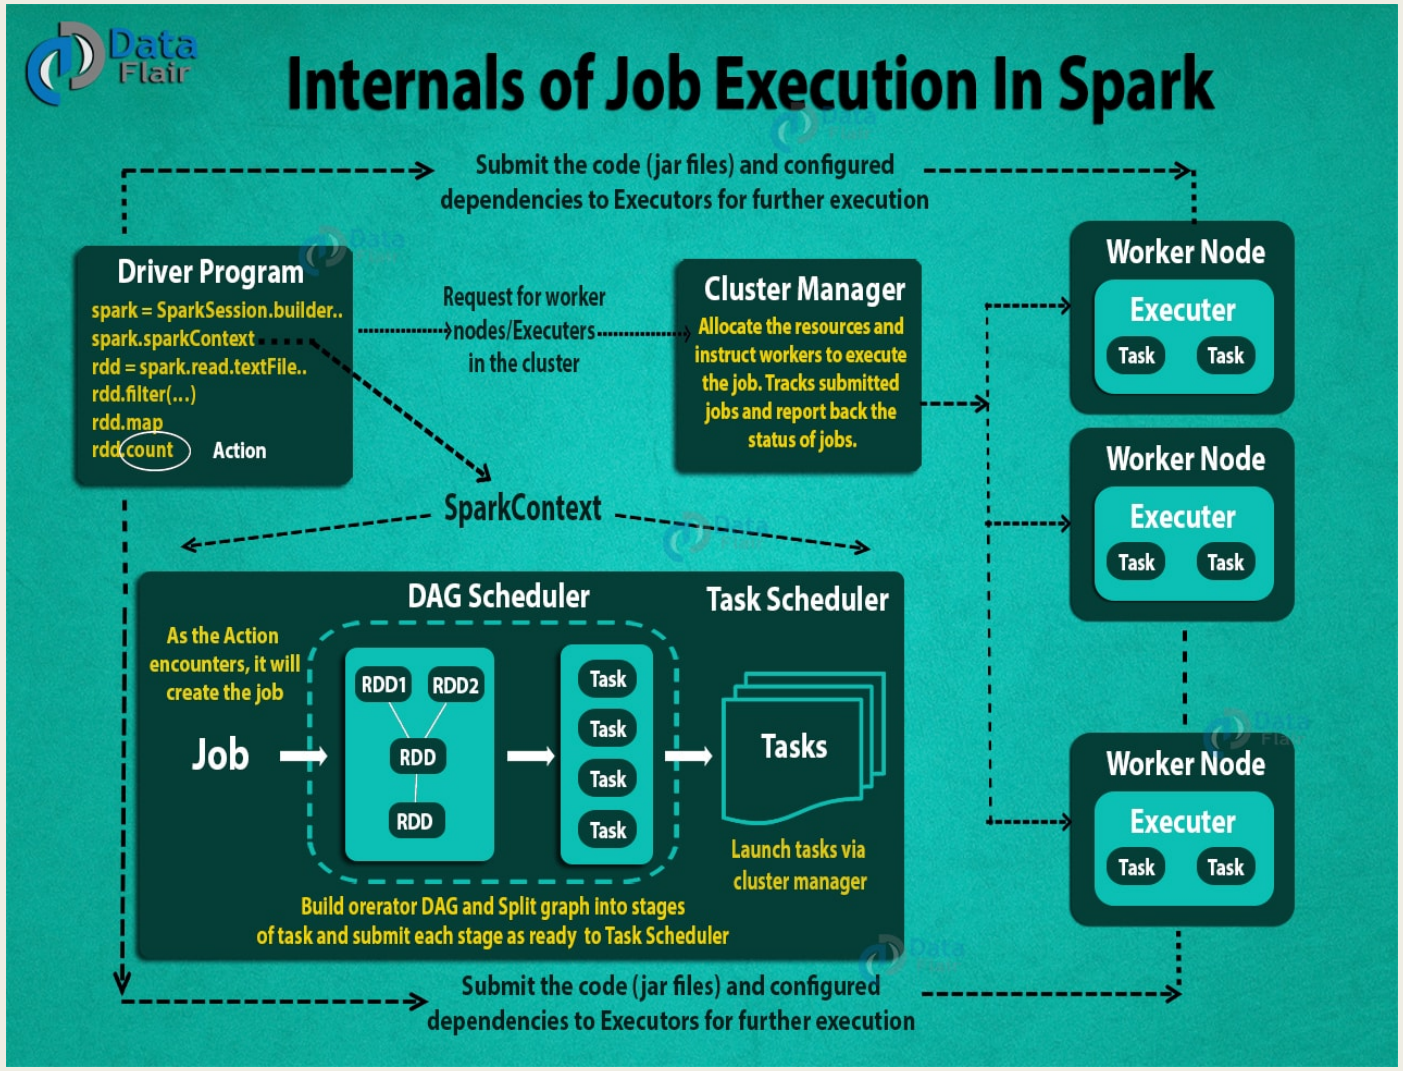
// Fit the pipeline to training documents.
val model = pipeline.fit(training)

 // Now we can optionally save the fitted pipeline to disk
model.write.overwrite().save("/tmp/spark-logistic-regression-model")

// Make predictions on test documents.
model.transform(test)
```

Relating back to YARN





https://data-flair.training/blogs/how-apache-spark-works/

Client vs Cluster mode

- Client mode – the driver runs in the client process on local machine, and the application master is only used for requesting resources from YARN.

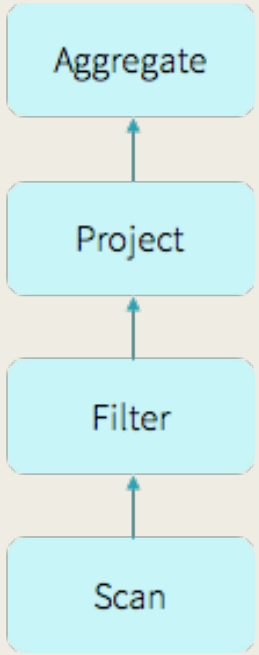
- Cluster mode – the Spark driver runs inside an application master process which is managed by YARN on the cluster, and the client can go away after initiating the application.

$ ./bin/spark-submit --class path.to.your.Class --master yarn --deploy-mode cluster [options] <app jar> [app options]

$ ./bin/spark-shell --master yarn --deploy-mode client

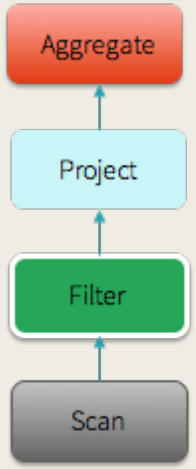
Code generation re-visted

```
select count(*) from store_sales
where ss_item_sk = 1000
```



Generic vs hand-written code

```
class Filter(child: Operator, predicate:
(Row => Boolean)) extends Operator {
   def next(): Row = {
     var current = child.next()
     while (current != null && !
predicate(current)) {
       current = child.next()
     }
     return current
   }
}
```



```
long count = 0;
for (ss_item_sk in store_sales) {
  if (ss_item_sk == 1000) {
    count += 1;
  }
}
```

Summary – SPARK vs MR

- Ease of use
- Developer productivity
- Speed
- Ecosystem: Spark R, Spark MLLib, PySpark, SparkSQL
- Lot of apache projects also moving to support/leverage Spark
